# <u>Input</u>

1. data.txt (.fasta etc )

First line -- all the classes presented in data that should be used in classification splitted by ','. Then sequences with metadata splitted by "\n". Each meta begins with '>' or another special symbol that is not presented anywhere else in file

class1,class2 ...
>meta1
sequence1
>meta2
sequence2
...

2. grammar.yrd

## **Modules description**

### Data Preprocessing

- Filter
- GetSelection
  - o for parsing
  - for\_NN1
  - o for NN2
- · EqualiseLength

- Filter -- user-defined, optional function, e.g. remove unclassified organisms
- GetSelection -- proportional selection of the existing data samples including the train:validation:test splitting
- EqualiseLength -- cut input sequences or add special symbol til the same length

#### Parsing

(sequences db -> num vectors db)

Console utility that converts sequences database to numerical vectors database.

Input parameters: input file, grammar, output file

#### Neural Network 1

(vector -> class)

Establishes a correspondence between the numerical vector and the class of the sequence this vector was obtained from

#### Neural Network 2

(sequence -> class)

Establishes a correspondence between the sequence and its class using the weights of NN1 in the following way: sequence -> vector -> class

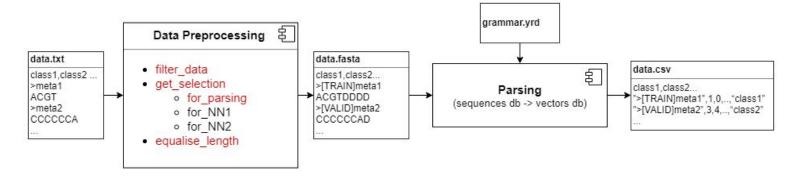

**Testing Module** 

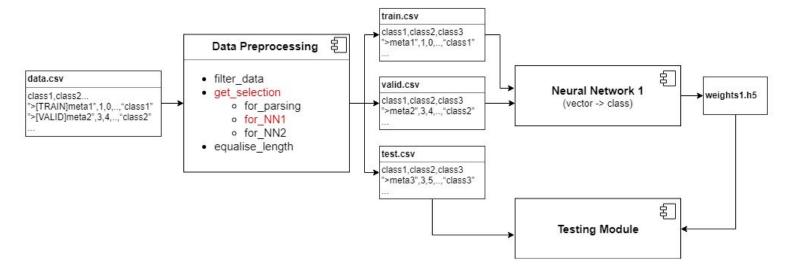

Neural networks test automation...?

### Workflow

## 1. Parsing

### 2. Neural Network 1 training and testing

# 3. Neural Network 2 training and testing
